#### SPECIFICATION

Molybdenum for structural material purposes

# 2. Scope of the Patent Claims

- 1. Molybdenum for structural material purposes, characterized in that from 1 to 5 wt% of lanthanum oxide  $(La_2O_3)$  is dispersed uniformly in molybdenum (Mo), and the average particle size of said dispersed lanthanum oxide  $(La_2O_3)$  is not more than 3  $\mu$ m and the maximum particle size is not more than 7  $\mu$ m.
- 2. Molybdenum for structural material purposes, according to Claim 1, where a sinter comprising molybdenum (Mo) powder and lanthanum oxide (La<sub>2</sub>O<sub>3</sub>) powder has been subjected to working with a working factor of at least 60%.

# 3. Detailed Description of the Invention

## Technical Field of the Invention

The invention concerns molybdenum for structural material purposes where La<sub>2</sub>O<sub>1</sub> particles are uniformly dispersed in Mo.

## Prior Art of the Invention and Associated Problems

Mo material in which La<sub>2</sub>O<sub>2</sub> is included is supplied mainly as a coil-like (spiral-like) wire or as a plate formed into a round cone as a cathode material for electron tubes.

The La<sub>2</sub>O<sub>3</sub> in the Mo does not form a solid solution and a compound with the Mo in the same way as the ThO<sub>2</sub> in thorium oxide-containing tungsten (ThO<sub>2</sub>-W) and it is dispersed as La<sub>2</sub>O<sub>3</sub> particles in the Mo.

Consequently, the various characteristics of such molybdenum materials are greatly affected not only by the La<sub>2</sub>O<sub>3</sub> particle content but also by the state of dispersion of the particles. For example, in cases where the La<sub>2</sub>O<sub>3</sub> in the Mo aggregates and the state of dispersion of the La<sub>2</sub>O<sub>3</sub> particles is poor problems arise in that failure often occurs, or cracks are formed, on

secondary working of the material such as when forming a coil or a cone for example.

Furthermore, if the state of dispersion of the La<sub>2</sub>O<sub>3</sub> in the Mo is poor, as mentioned above, then various problems arise when the material is used as the cathode material for an electron tube in that it is difficult to achieve good electron release characteristics and the life expectancy is short.

Hence, in the past it has been impossible to resolve the various problems associated with workability and electron release characteristics, for example, as mentioned above since the appropriate dispersion state of the La<sub>2</sub>O<sub>3</sub> added to the molybdenum material was unknown.

## Purpose of the Invention

The aim of the present invention is to resolve the abovementioned problems by supplying Mo material which contains from 1 to 5 wt% of La<sub>2</sub>O<sub>3</sub> which, when used as a structural material, can be subjected easily to secondary working and which, when used as a cathode material, has a long life.

## Outline of the Invention

As a result of thorough research carried out with a view to achieving the abovementioned aim, the inventors have discovered that if, in a Mo material which contains from 1 to 5 wt% of La<sub>2</sub>O<sub>3</sub>, the La<sub>2</sub>O<sub>3</sub> particles are uniformly and finely dispersed, the various properties such as the secondary working properties and the electron release characteristics are improved, and the invention is based upon this discovery.

The molybdenum for structural purposes of this invention is characterized in that from 1 to 5 wt% lanthanum oxide ( $La_2O_3$ ) is uniformly dispersed in molybdenum (Mo) and the average particle size of said dispersed lanthanum oxide ( $La_2O_3$ ) particles is not more than 3  $\mu$ m and the maximum particle size is not more than 7  $\mu$ m.

In this invention the La<sub>2</sub>O<sub>3</sub> is a component which provides an electron release function and increases the high temperature strength.

The La<sub>2</sub>O<sub>3</sub> content is set at from 1 to 5 wt%. If the La<sub>2</sub>O<sub>3</sub> content is less than 1 wt% then the effect of adding La<sub>2</sub>O<sub>3</sub> is unlikely to be achieved and characteristics approaching those of pure Mo are exhibited, and if the content exceeds 5 wt% then little change over the effect observed on adding not more than 5 wt% is seen and, moreover, there are problems in that, for example, the secondary working properties become poor.

The particle size of the La $_2$ O $_3$  must be not more than 3  $\mu$ m as an average particle size and not more than 7  $\mu$ m as a maximum particle size. If the average particle size exceeds 3  $\mu$ m or if the maximum particle size exceeds 7  $\mu$ m then not only are the working properties adversely affected in that failure may occur or cracks may be formed on secondary working a wire or sheet, but when the material is used as the cathode material in an electron tube it is difficult to achieve stable electron release characteristics over a long period of time.

Moreover, the secondary working properties of a wire or sheet material are affected by the working factor (fractional change in the cross sectional area) from a sinter comprising molybdenum (Mo) and lanthanum oxide (La<sub>2</sub>O<sub>3</sub>) as well as the content and state of dispersion of the La<sub>2</sub>O<sub>3</sub>.

Molybdenum for structural purposes of this invention is preferably worked with a working factor from the sinter of at least 60%. Metals like Mo which, when compared with Cu and Al, are brittle, are such that the non-orientated crystal structure produced by sintering can be formed into a crystal structure which is orientated in the working direction by working. The flexibility of the molybdenum for structural purposes is improved by forming such an aggregate structure. According to the results of experiments carried out by the inventors, with Mo material which contains from 1 to 5 wt% La<sub>2</sub>O<sub>1</sub>, secondary working becomes easier as the working factor from the sinter

becomes great, and there is no problem in ractice with wire or sheet material where the working factor is at least 60%.

## Embodiment of the Invention

The characteristics of Mo materials containing from 1 to 5 wt% of La,O, of this invention are described below.

Pressed-powder mouldings were made with a pressure 1.5 ton/cm2 using a mechanical press in accordance with the methods of powder metallurgy while varying the amount of La,O, added and the method of mixing in such a way that the La,O, content was 0.5, 1.0, 2.0, 4.0 or 6.0 wt% and the particle size of the La,O, differed, and the pressed-powder mouldings were sintered for 8 hours at 1850°C in a hydrogen atmosphere. sinters obtained at this time were of specific gravity about 9.50, and there were of a form of cross section 12 x 12 mm and length 650 mm. The sinters were subjected to beating and drawing while applying heat and wires of 0.60 mm were Verification of the La<sub>2</sub>O<sub>2</sub> particle size in the Mo obtained. wires was carried out by embedding the wire in a thermoset resin and providing a mirror surface finish with the usual polishing method and then just the Mo material was polished away using a special electrolytic polishing method so that the La<sub>2</sub>O, was left behind above the polished surface and then the particles were observed using a scanning electron microscope.

The relationships between the La<sub>2</sub>O<sub>3</sub> content in the Mo in the 0.60 mm¢ diameter wires and the maximum La<sub>2</sub>O<sub>3</sub> particle size with the flexibility of the wire and secondary recrystallization temperature are shown in Table 1.

Table 1

La.O.	-															•

0.6 mm¢ (°C)		<u> </u>	<del></del>							•						1320
																37

As is clear these results, an  $La_2O_3$  count of from 1.0 to 5 wt% is best, and according to the experimental results obtained by the inventors an  $La_2O_3$  content of from 2 to 3 wt% is ideal. Furthermore, a smaller  $La_2O_3$  particle size is better, and the secondary working properties decline sharply if the particle size exceeds 8  $\mu$ m.

Furthermore, the abovementioned pressed-powder mouldings were pressed at a hydrostatic pressure of 2 ton/cm² to mould pressed powder-mouldings and sinters of specific gravity 9.45 and with a shape of diameter 60 mm¢ and length 400 mm obtained by sintering for 8 hours at 1850°C in a hydrogen atmosphere were hammer worked and roll worked and sheets of thickness 0.2 mm were obtained. At this time an intermediate heat treatment above the secondary recrystallization temperature was carried out in a hydrogen atmosphere. The dimensions of the sheet material which was heat-treated were such that the working factor to work to a sheet thickness of 0.2 mm was 40%, 60% or 80%. The results obtained on investigating the flexibility of the sheet materials at this time are shown in Table 2.

Table 2

	Working	Fact	or (%)		·	40	60	80
Flex	Properties	of	0.2	t	sheet	1.5	10	20
mater	ial (Relativo	e Val	ues)					

<sup>\*</sup> Amount of La<sub>2</sub>O<sub>3</sub> added: 2%
Maximum particle size of the La<sub>2</sub>O<sub>3</sub>: 2.0 μm

As is clear from these results, the effect on the flexibility of the working factor is similar to that in the case of a wire where it is known that good flexibility is obtained on working by at least 60%

Next, the relationship between the La<sub>2</sub>O<sub>3</sub> content in the Mo used in an electron tube (wire diameter 0.2 mm¢) and the electron release characteristics is shown in Table 3. According to Table 3 an La<sub>2</sub>O<sub>3</sub> content of at least 1.0 wt% is required, and there is no improvement in the electron release characteristics even if the La<sub>2</sub>O<sub>3</sub> content exceeds 6.0 wt%, there being a slight

fall when dered with the characterists obtained with 2 wt%.

characteristics are obtained)				

# Effect of the Invention

As is clear from the description above, the molybdenum for structural purposes of this invention provides the following excellent effects: (1) it has good secondary working properties, (2) it has a high secondary recrystallization temperature and so has high high-temperature strength, and (3) it has stable electron release characteristics, and it is of very great industrial value.

[発明の技術分野]

本発明は、La<sub>2</sub>O<sub>5</sub>粒子がMo中に均一に分散され た構造材料用のモリプデンに関する。

[ 発明の技術的背景とその問題点]

La2Osを含有せる Mo 材は、主に餌子管の除板材

として、コイル状(スパイラル状)の線または板 を丸めた円筒として供される。

ところで、Mo 中の La<sub>2</sub>O<sub>3</sub> は酸化トリウム入りタングステン (ThO<sub>2</sub>-W)中の ThO<sub>2</sub> と同様に Mo と固溶したり化合物を形成することなく、Mo 中に La<sub>2</sub>O<sub>3</sub>の粒子として分散されている。

このため、このようなモリプデン材料の賭特性は、 La<sub>2</sub>O<sub>3</sub> 粒子の含有量のみならず、その分散状態の影響を大きく受ける。

例えば、Mo 中の La<sub>2</sub>O<sub>3</sub>が凝集している等、La<sub>2</sub>O<sub>3</sub> 粒子の分散状態が悪い場合にはコイル状あるいは 円筒状に賦形する等の二次加工を施す際に、しば しば断線したり、亀裂を生じるという問題が生じ

また、上配の如く Mo 中の LagOs の分散状態が悪いと、電子管の陰極材として用いた場合には良好な電子放出特性が得られにくく、しかも短寿命となるという額々の問題があつた。

しかしながら、従来、モリプデン材料に添加すべき La.O. の適切な分散状態が知られていなかつ

たため、上記加工性、電子放射特性などの時間題 を解決することができなかった。

#### 〔 発明の目的 〕

本発明の目的は、上配問題点を解消し、構造材として用いた場合には容易に二次加工ができ、しかも侃子質の彫模材として用いた場合には長寿命となる La,O, を 1 ~ 5 批散を含有する Mo 材を提供することにある。

#### 〔発明の概要〕

本発明省らは上記目的を遊成すべく、鋭意研究を爪ねた結果、 La<sub>2</sub>O<sub>3</sub>を 1 ~ 5 取損 % 含有する Mo 材において、 Mo 中に La<sub>2</sub>O<sub>3</sub>粒子を均一かつ 級細に 分散せしめると、その二次加工性、 電子放出特性 等の緒特性が改善されることを見出し、本発明を 完成した。

本発明の構造材用モリプデンは、モリプデン (Mo)中に1~5 旗景多の酸化ランタン (La<sub>2</sub>O<sub>3</sub>)が均一に分散されており、設分散された酸化ランタン (La<sub>2</sub>O<sub>3</sub>)の個々の平均粒径が3 μm 以下であつて、かつ、超大粒径が7 μm 以下であることを

特徴とする。

本発明におり La<sub>2</sub>O。は恨子放出能を与え、 かつ、高温強度を高める成分である。

La<sub>2</sub>O<sub>3</sub> の含有量は 1 ~ 5 取景 8 とする。 La<sub>2</sub>O<sub>3</sub> の含有量が 1 多未満の 場合は La<sub>2</sub>O<sub>3</sub> の添加効果が得られにくく、純 Mo に近い特性を示し、5 多を超えた場合は、5 多以下の添加効果と、さほど大きな変化が認められず、しかも、二次加工性が悪くなる等の問題点を生じる。

La<sub>2</sub>O<sub>3</sub> の粒子径は平均粒径で3 μm 以下であり、かつ、最大粒径で7 μm 以下でなければならない。平均粒径が3 μm を超えるか、または、最大粒径が7 μm を超えると、綴または板を二次加工する際に断線したり、 鬼殺が入る等、 等じるしく加工性が低下するばかりでなく、 電子管の降極材料として用いた場合、 長時間安定な電子放出特性を得ることが困難となる。

更に、線あるいは板材の二次加工性は、La<sub>2</sub>O<sub>3</sub>の含有量、分散形態の他に、モリプデン(Mo)と酸化ランタン(La<sub>2</sub>O<sub>3</sub>)からなる焼結体からの加工

翠(横断而積の変化率)に影響される。

本発明の構造材用モリプデンは、好きしくは、 続結体からの加工率609以上で加工された較して加工等609以上で加工等とCu・AL等性のしてある。Moのでで、もともとCu・AL等性のして、もともとCu・AL等性のして、もともとCu・AL等性のして、もともとCu・AL等性の加工をでは、加工する。とによってといる。というでは、一般のでは、一般のでは、一般のでは、一般によれば、一般のでは、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般によれば、一般にない。

#### ( 発明の実施例 )

以下本発明のLa<sub>2</sub>O、1~5 放射多合有せる Mo 材の特徴を説明する。

粉末治金法によつて La<sub>2</sub>O<sub>3</sub> 含有紙を 0.5 , 1.0 , 2.0 , 4.0 , 6.0 取触 5 、 さらに La<sub>2</sub>O<sub>3</sub> 粒径に差が出る様、磁加量、混合方法を変え、機械プレス
